1 Introduction

I think that Boost.Graph is designed very well. Drawback is IMHO that there are only few and even fewer complete examples using Boost.Graph.

The book [1] is IMHO not suited best for a tutorial as it contains heavy templated code, and an unchronological ordering of subjects. More experienced programmers can appreciate that the authors took great care that the code snippets written in the book were correct: all snippets are numbered, and I'd bet they are tested to compile.

1.1 Coding style used

I use the coding style from the Core C++ Guidelines.

I prefer not to use the keyword `auto`, but to explicitly mention the type instead. I think this is beneficial to beginners. When using Boost.Graph in production code, I do prefer to use `auto`.

OTOH, while writing this tutorial, I use `auto` when I loose too much time figuring out the type

All coding snippets are taken from compiled C++ code.

1.2 Pitfalls

The choice between `'boost::get'`, `'std::get'` and `'get'`. AFAIKS, when in doubt, use `'get'`.

2 Building graphs

Boost.Graph is about creating graphs. In this chapter we create graphs, starting from simple to more complex.

2.1 Creating an empty graph

Let's create a trivial empty graph:

Algorithm 1 Creating an empty graph

```
#include "create_empty_graph.h"

boost::adjacency_list<
create_empty_graph() noexcept
{
    return boost::adjacency_list<>();
}
```

Congratulations, you've just created a `boost::adjacency_list` in which:

- The out edges are stored in a `std::vector`
- The vertices are stored in a `std::vector`
- The graph is directed
- Vertices, edges and graph have no properties
- Edges are stored in a `std::list`

The `boost::adjacency_list` is the most commonly used graph type, the other is the `boost::adjacency_matrix`.

2.2 Add a vertex

To add a vertex to a graph, the `boost::add_vertex` function is used as such:

Algorithm 2 Adding a vertex to a graph

```
#include <boost/graph/adjacency_list.hpp>

template <typename graph>
void add_vertex(graph& g)
{
    boost::add_vertex(g);
}
```

Note that `boost::add_vertex` returns a vertex descriptor, which is ignored for now. This vertex descriptor can be used to connect two vertices by an edge

2.3 Add an edge

To add an edge to a graph, two vertex descriptors are needed. Algorithm 3 adds two vertices to a graph, and connects these two using `boost::add_edge`:

Algorithm 3 Adding (two vertices and) an edge to a graph

```
#include <boost/graph/adjacency_list.hpp>

#include <cassert>

template <typename graph>
void add_edge(graph& g)
{
    using boost::graph_traits;
    using vertex_descriptor
        = typename graph_traits<graph>::vertex_descriptor;
    using edge_descriptor
        = typename graph_traits<graph>::edge_descriptor;
    using edge_insertion_result
        = std::pair<edge_descriptor, bool>;

    const vertex_descriptor va = boost::add_vertex(g);
    const vertex_descriptor vb = boost::add_vertex(g);
    const edge_insertion_result ea
        = boost::add_edge(va, vb, g);

    assert(ea.second);
}
```

Note that half of the code consists out of using statements. This algorithm only shows how to add an isolated edge to a graph, instead of allowing for graphs with higher connectivities. The function `boost::add_edge` returns a pair, consisting of an edge descriptor and a boolean success indicator. In algorithm 3 we assert that insertion was successful. Insertion can fail if an edge is already present and duplicates are not allowed.

2.4 Creating K_2 , a fully connected graph with two vertices

To create a fully connected graph with two vertices (also called K_2), one needs two vertices and one (undirected) edge, as depicted in figure 1.

Figure 1: K_2 : a fully connected graph with two vertices named a and b

To create K_2 , the following code can be used:

Algorithm 4 Creating K_2 as depicted in figure1

```
#include "create_k2_graph.h"

boost::adjacency_list<
    boost::vecS,
    boost::vecS,
    boost::undirectedS
>
create_k2_graph() noexcept
{
    using boost::graph_traits;

    using graph = boost::adjacency_list<
        boost::vecS,
        boost::vecS,
        boost::undirectedS
    >;

    using vertex_descriptor
        = typename graph_traits<graph>::vertex_descriptor;
    using edge_descriptor
        = typename graph_traits<graph>::edge_descriptor;
    using edge_insertion_result
        = std::pair<edge_descriptor, bool>;

    graph g;
    const vertex_descriptor va = boost::add_vertex(g);
    const vertex_descriptor vb = boost::add_vertex(g);
    const edge_insertion_result ea
        = boost::add_edge(va, vb, g);
    assert(ea.second);
    return g;
}
```

Note that this code has more lines of using statements than actual code! In this code, the third template argument of `boost::adjacency_list` is `boost::undirectedS`, to select (that is what the S means) for an undirected graph. Adding a vertex with `boost::add_vertex` results in a vertex descriptor, which is a handle to the vertex added to the graph. Two vertex descriptors are then used to add an edge to the graph. Adding an edge using `boost::add_edge` returns two things: an edge descriptor and a boolean indicating success. In the code example, we assume insertion is successful.

Note that the graph lacks all properties: nodes do not have names, nor do edges.

2.5 Creating an empty graph with named vertices

Let's create a trivial empty graph, in which the vertices can have a name:

Algorithm 5 Creating an empty graph

```
#include <boost/graph/adjacency_list.hpp>

template <typename graph>
void add_named_vertex(graph& g, const std::string& name)
{
    using boost::graph_traits;
    using boost::property_map;
    using boost::vertex_name_t;
    using vertex_descriptor
        = typename boost::graph_traits<graph>::
            vertex_descriptor;
    using vertex_iterator
        = typename graph_traits<graph>::vertex_iterator;
    //using vertex_iterators
    // = std::pair<vertex_iterator, vertex_iterator>;
    using name_map_t
        = typename property_map<graph, vertex_name_t>::type;

    vertex_descriptor vd{
        boost::add_vertex(g)
    };

    name_map_t name_map{boost::get(boost::vertex_name, g)};
    name_map[vd] = name;

    /*
    const auto name_map = get(boost::vertex_name, g);

    vertex_iterators vi = vertices(g);
    —vi.second;
    put(name_map, *vi.second, name);
    */
}
```

wef

2.6 Add a vertex with a name

Adding a vertex without a name was trivially easy (see chapter 2). Adding a vertex with a name is less easy:

Algorithm 6 Creating an empty graph

```
#include <boost/graph/adjacency_list.hpp>

boost::adjacency_list<
    boost::vecS,
    boost::vecS,
    boost::undirectedS,
    boost::property<
        boost::vertex_name_t, std::string
    >
>
>
create_empty_named_vertices_graph() noexcept
{
    using graph = boost::adjacency_list<
        boost::vecS,
        boost::vecS,
        boost::undirectedS,
        boost::property<
            boost::vertex_name_t, std::string
        >
    >;

    graph g;
    return g;
}
```

Instead of calling 'boost::add_vertex' with an additional argument containing the name of the vertex, multiple things need to be done. After adding a new vertex to the graph, the graph's name map is obtained, which contains all the vertices' names. To set the new vertex's name in the name map, an iterator to the newly added vertex is needed. boost::vertices is used to obtain an iterator pair. The second iterator of that pair points beyond the last vertex, so decrementing it makes it point to the new vertex. Finally, 'put' is used to set the name.

2.7 Creating K_2 with named vertices

We extend K_2 of chapter 2.4 by naming the vertices 'from' and 'to', as depicted in figure 2:

Figure 2: K_2 : a fully connected graph with two vertices with the text 'from' and 'to'

To create K_2 , the following code can be used:

Algorithm 7 Creating K_2 as depicted in figure 2

```
#include "create_named_vertices_k2_graph.h"

boost::adjacency_list<
    boost::vecS,
    boost::vecS,
    boost::undirectedS,
    boost::property<boost::vertex_name_t, std::string>
>
create_named_vertices_k2_graph() noexcept
{
    using graph = boost::adjacency_list<
        boost::vecS,
        boost::vecS,
        boost::undirectedS,
        boost::property<
            boost::vertex_name_t, std::string
        >
    >;
    using vertex_descriptor
        = typename boost::graph_traits<graph>::
            vertex_descriptor;
    using edge_descriptor
        = typename boost::graph_traits<graph>::
            edge_descriptor;
    using edge_insertion_result
        = std::pair<edge_descriptor, bool>;
    using name_map_t
        = boost::property_map<graph, boost::vertex_name_t>::
            type;

    graph g;
    const vertex_descriptor va = boost::add_vertex(g);
    const vertex_descriptor vb = boost::add_vertex(g);
    const edge_insertion_result ea
        = boost::add_edge(va, vb, g);
    assert(ea.second);

    //Add names
    name_map_t name_map{boost::get(boost::vertex_name, g)};
    name_map[va] = "from";
    name_map[vb] = "to";

    return g;
}
```

Most of the code is a repeat of algorithm 4. In the end, the names are obtained as a `boost::property_map` and set.

2.8 Add an edge with a name

2.9 Creating K_3 with named edges and vertices

We extend the graph K_2 with named vertices of chapter 2.7 by adding names to the edges, as depicted in figure 3:

Figure 3: K_3 : a fully connected graph with three named edges and vertices

To create K_3 , the following code can be used:

Algorithm 8 Creating K_3 as depicted in figure 3

```
#include "create_named_edges_and_vertices_k3_graph.h"

boost::adjacency_list<
    boost::vecS,
    boost::vecS,
    boost::undirectedS,
    boost::property<boost::vertex_name_t, std::string>,
    boost::property<boost::edge_name_t, std::string>
>
create_named_edges_and_vertices_k3_graph() noexcept
{
    using graph = boost::adjacency_list<
        boost::vecS,
        boost::vecS,
        boost::undirectedS,
        boost::property<
            boost::vertex_name_t, std::string
        >,
        boost::property<
            boost::edge_name_t, std::string
        >
    >;
    using vertex_descriptor
        = typename boost::graph_traits<graph>::
            vertex_descriptor;
    using edge_descriptor
        = typename boost::graph_traits<graph>::
            edge_descriptor;
    using edge_insertion_result
        = std::pair<edge_descriptor, bool>;
    using vertex_name_map_t
        = boost::property_map<graph, boost::vertex_name_t>::
            type;
    using edge_name_map_t
        = boost::property_map<graph, boost::edge_name_t>::type
        ;

    graph g;
    const vertex_descriptor va = boost::add_vertex(g);
    const vertex_descriptor vb = boost::add_vertex(g);
    const vertex_descriptor vc = boost::add_vertex(g);
    const edge_insertion_result eab
        = boost::add_edge(va, vb, g);
    assert(eab.second);
    const edge_insertion_result ebc
        = boost::add_edge(vb, vc, g);
    assert(ebc.second);
    const edge_insertion_result eca
        = boost::add_edge(vc, va, g);
    assert(eca.second);

    //Add vertex names
    vertex_name_map_t vertex_name_map{boost::get(boost::
        vertex_name, g)};
```

Most of the code is a repeat of algorithm 7. In the end, the edge names are obtained as a `boost::property_map` and set.

2.10 Add a custom vertex

2.11 Creating K_2 with custom vertices

Instead of using vertices with a name, or other properties, here we use a custom vertex class called `'my_vertex'`. A `'my_vertex'` has an x coordinat, y coordinat, a name and a description.

2.12 Add a custom edge

2.13 Creating K_2 with custom edges and vertices

Instead of using edges with a name, or other properties, here we use a custom edge class called `'my_edge'`.

3 Measuring simple graphs traits

Measuring simple traits of the graphs created allows you to debug your code.

3.1 Getting the vertices

You can use `boost::vertices` to obtain an iterator pair. The first iterator points to the first vertex, the second points to beyond the last vertex.

3.2 Getting the edges

You can use `boost::edges` to obtain an iterator pair. The first iterator points to the first edge, the second points to beyond the last edge.

3.3 Counting the number of vertices

Use `boost::num_vertices`, as shown here:

Algorithm 9 Count the numbe of vertices

```
#ifndef GET_N_VERTICES_H
#define GET_N_VERTICES_H

#include <utility>
#include <boost/graph/adjacency_list.hpp>

///Get the number of vertices a graph has
template <class graph>
int get_n_vertices(const graph& g)
{
    return static_cast<int>(boost::num_vertices(g));
    /*
    using vertex_iterator
        = typename boost::graph_traits<graph>::
            vertex_iterator;
    using vertex_iterators
        = std::pair<vertex_iterator, vertex_iterator>;

    const vertex_iterators vertex_iters
        = boost::vertices(g);
    return std::distance(
        vertex_iters.first,
        vertex_iters.second
    );
    */
}

void get_n_vertices_test() noexcept;

#endif // GET_N_VERTICES_H
```

3.4 Counting the number of edges

Use boost::num_edges, as show here:

Algorithm 10 Count the number of edges

```
#ifndef GET_N_EDGES_H
#define GET_N_EDGES_H

#include <utility>
#include <boost/graph/adjacency_list.hpp>

///Get the number of edges a graph has
template <class graph>
int get_n_edges(const graph& g)
{
    return static_cast<int>(boost::num_edges(g));
    /*
    const auto edge_iters = boost::edges(g);
    return std::distance(edge_iters.first, edge_iters.second);
    */
}

void get_n_edges_test() noexcept;

#endif // GET_N_EDGES_H
```

3.5 Getting the vertices' names

When the vertices of a graph have named vertices, one can extract them as such:

Algorithm 11 Get the vertices' names

```
#ifndef GET_VERTEX_NAMES_H
#define GET_VERTEX_NAMES_H

#include <string>
#include <vector>
#include <boost/graph/graph_traits.hpp>
#include <boost/graph/properties.hpp>

//TODO: generalize to return any type
template <typename graph>
std::vector<std::string> get_vertex_names(const graph& g)
{
    using vertex_iterator
        = typename boost::graph_traits<graph>::
            vertex_iterator;
    using vertex_iterators
        = std::pair<vertex_iterator, vertex_iterator>;

    std::vector<std::string> v;

    //TODO: remove auto
    const auto name_map = get(boost::vertex_name, g);

    for (vertex_iterators p = vertices(g);
        p.first != p.second;
        ++p.first)
    {
        v.emplace_back(get(name_map, *p.first));
    }
    return v;
}

//TODO: generalize to return any type
template <typename graph>
std::vector<std::string> get_vertex_names_DOESNOTWORK(
    const graph& g)
{
    using vertex_iterator
        = typename boost::graph_traits<graph>::
            vertex_iterator;
    using vertex_iterators
        = std::pair<vertex_iterator, vertex_iterator>;
    using name_map_t
        = typename boost::property_map<graph, boost::
            vertex_name_t>::type;

    std::vector<std::string> v;15

    const name_map_t name_map = get(boost::vertex_name, g);

    for (vertex_iterators p = vertices(g);
        p.first != p.second;
        ++p.first)
    {
```

The names of the vertices are obtained from a `boost::property_map` and then put into a `std::vector`.

When trying to get the vertices' names from a graph without vertices with names, you will get the error 'formed reference to void' (for example, with the code `'get_vertex_names(create_k2_graph());'`).

3.6 Getting the edges' names

When the edges of a graph have named vertices, one can extract them as such:

Algorithm 12 Get the edges' names

```
#ifndef GET_EDGE_NAMES
#define GET_EDGE_NAMES

#include <string>
#include <vector>
#include <boost/graph/graph_traits.hpp>
#include <boost/graph/properties.hpp>

//TODO: generalize to return any type
template <typename graph>
std::vector<std::string> get_edge_names(const graph& g)
{
    using edge_iterator
        = typename boost::graph_traits<graph>::edge_iterator;
    using edge_iterators
        = std::pair<edge_iterator, edge_iterator>;

    std::vector<std::string> v;

    //TODO: remove auto
    const auto edge_name_map = get(boost::edge_name, g);

    for (edge_iterators p = edges(g);
        p.first != p.second;
        ++p.first)
    {
        v.emplace_back(get(edge_name_map, *p.first));
    }
    return v;
}

void get_edge_names_test() noexcept;

#endif // GET_EDGE_NAMES
```

The names of the edges are obtained from a `boost::property_map` and then put into a `std::vector`.

When trying to get the edges' names from a graph without vertices with names, you will get the error 'formed reference to void' (for example, with the code `'get_vertex_names(create_k2_graph());'`).

3.7 Find a vertex by its name

3.8 Replace a vertex its name

4 Modifying simple graphs traits

It is useful to be able to modify every aspect of a graph. Adding nodes and edges are found in earlier chapters.

4.1 Setting all vertices' names

When the vertices of a graph have named vertices, one set their names as such:

Algorithm 13 Setting the vertices' names

```
#ifndef SET_VERTEX_NAMES_H
#define SET_VERTEX_NAMES_H

#include <string>
#include <vector>

#include <boost/graph/graph_traits.hpp>
#include <boost/graph/properties.hpp>

//TODO: generalize 'names'
template <typename graph>
void set_vertex_names(
    graph& g,
    const std::vector<std::string>& names
)
{
    using vertex_iterator
        = typename boost::graph_traits<graph>::
            vertex_iterator;
    using vertex_iterators
        = std::pair<vertex_iterator, vertex_iterator>;

    const auto name_map = get(boost::vertex_name, g);

    auto names_begin = std::begin(names);
    const auto names_end = std::end(names);
    for (vertex_iterators vi = vertices(g);
        vi.first != vi.second;
        ++vi.first, ++names_begin)
    {
        assert(names_begin != names_end);
        put(name_map, *vi.first, *names_begin);
    }
}

void set_vertex_names_test() noexcept;

#endif // SET_VERTEX_NAMES_H
```

An impressive feature is that getting the property map holding the graph its names is not a copy, but a reference. Otherwise, modifying 'name_map'

(obtained by non-reference) would only modify a copy.

5 Visualizing graphs

Before graphs are visualized, they are stored as a file first. Here, I use the .dot file format.

5.1 Storing a graph as a .dot

Graph are easily saved to a .dot file:

Algorithm 14 Storing a graph as a .dot file

```
#ifndef SAVE_GRAPH_TO_DOT_H
#define SAVE_GRAPH_TO_DOT_H

#include <fstream>
#include <boost/graph/graphviz.hpp>

///Save a graph to a .dot file
template <typename graph>
void save_graph_to_dot(const graph& g, const std::string&
    filename)
{
    std::ofstream f(filename);
    boost::write_graphviz(f,g);
}

void save_graph_to_dot_test() noexcept;

#endif // SAVE_GRAPH_TO_DOT_H
```

Using the `create_k2_graph` function (algorithm 4) to create a K_2 graph, the .dot file created is displayed in algorithm 15:

Algorithm 15 .dot file created from the `create_k2_graph` function (algorithm 4)

```
graph G {
0;
1;
0--1 ;
}
```

This .dot file corresponds to figure 4:

Figure 4: .svg file created from the `create_k2_graph` function (algorithm 4)

If you used the `create_named_vertices_k2_graph` function (algorithm 7) to produce a K_2 graph with named vertices, you see that the .dot file does not have stored the vertex names:

Algorithm 16 .dot file created from the `create_named_vertices_k2_graph` function (algorithm 7)

```

graph G {
0;
1;
0--1 ;
}

```

So, the 'save_graph_to_dot' function (algorithm 14) saves the structure of the graph.

5.2 Storing a graph with named vertices as a .dot

If you used the `create_named_vertices_k2_graph` function (algorithm 7) to produce a K_2 graph with named vertices, you can store these names additionally with algorithm 17:

Algorithm 17 Storing a graph with named vertices as a .dot file

```
#ifndef SAVE_NAMED_VERTICES_GRAPH_TO_DOT_H
#define SAVE_NAMED_VERTICES_GRAPH_TO_DOT_H

#include <string>
#include <fstream>
#include <boost/graph/graphviz.hpp>
#include <boost/graph/properties.hpp>

#include "get_vertex_names.h"

///Save a graph with named vertices to a .dot file
template <typename graph>
void save_named_vertices_graph_to_dot(const graph& g,
    const std::string& filename)
{
    std::ofstream f(filename);
    const auto names = get_vertex_names(g);
    boost::write_graphviz(f, g, boost::make_label_writer(&
        names[0]));
}

void save_named_vertices_graph_to_dot_test() noexcept;

#endif // SAVE_NAMED_VERTICES_GRAPH_TO_DOT_H
```

The .dot file created is displayed in algorithm 18:

Algorithm 18 .dot file created from the create_named_vertices_k2_graph function (algorithm 7)

```
graph G {
0[label=from];
1[label=to];
0--1 ;
}
```

This .dot file corresponds to figure 5:

Figure 5: .svg file created from the `create_k2_graph` function (algorithm 7)

If you used the `create_named_edges_and_vertices_k3_graph` function (algorithm 8) to produce a K_3 graph with named edges and vertices, you see that the .dot file does not have stored the edge names:

Algorithm 19 .dot file created from the `create_named_edges_and_vertices_k3_graph` function (algorithm 8)

```

graph G {
0[label=top];
1[label=right];
2[label=left];
0--1 ;
1--2 ;
2--0 ;
}

```

So, the 'save_named_vertices_graph_to_dot' function (algorithm 14) saves only the structure of the graph and its vertex names.

5.3 Storing a graph with named vertices and edges as a .dot

If you used the `create_named_edges_and_vertices_k3_graph` function (algorithm 8) to produce a K_3 graph with named edges and vertices, you can store these names additionally with algorithm 20:

Algorithm 20 Storing a graph with named edges and vertices as a .dot file

```
#ifndef SAVE_NAMED_EDGES_AND_VERTICES_GRAPH_TO_DOT
#define SAVE_NAMED_EDGES_AND_VERTICES_GRAPH_TO_DOT

#include <string>
#include <fstream>
#include <boost/graph/graphviz.hpp>
#include <boost/graph/properties.hpp>

#include "get_edge_names.h"
#include "get_vertex_names.h"

///Save a graph with named vertices to a .dot file
template <typename graph>
void save_named_edges_and_vertices_graph_to_dot(const
    graph& g, const std::string& filename)
{
    std::ofstream f(filename);
    const auto vertex_names = get_vertex_names(g);
    const auto edge_name_map = boost::get(boost::edge_name,
        g);
    boost::write_graphviz(
        f,
        g,
        boost::make_label_writer(&vertex_names[0]),
        [edge_name_map](std::ostream& out, const auto& e) {
            out << "[label=" << edge_name_map[e] << "]" ;
        })
    );
}

void save_named_edges_and_vertices_graph_to_dot_test()
    noexcept;

#endif // SAVE_NAMED_EDGES_AND_VERTICES_GRAPH_TO_DOT
```

The .dot file created is displayed in algorithm 21:

Algorithm 21 .dot file created from the create_named_edges_and_vertices_k3_graph function (algorithm 7)

```
graph G {
0[label=top];
1[label=right];
2[label=left];
0--1 [label=AB];
1--2 [label=BC];
2--0 [label=CA];
}
```

This .dot file corresponds to figure 6:

Figure 6: .svg file created from the create_named_edges_and_vertices_k3_graph function (algorithm 7)

If you used the MORE_COMPLEX_create_named_edges_and_vertices_k3_graph function (algorithm 8) to produce a K_3 graph with named edges and vertices, you see that the .dot file does not have stored the edge names:

Algorithm 22 .dot file created from the
MORE_COMPLEX_create_named_edges_and_vertices_k3_graph function (algorithm 8)

```
graph G {  
0[label=top];  
1[label=right];  
2[label=left];  
0--1 [label=AB];  
1--2 [label=BC];  
2--0 [label=CA];  
}
```

So, the 'save_named_edges_and_vertices_graph_to_dot' function (algorithm 14) saves only the structure of the graph and its edge and vertex names.

6 TODO's in general

6.1 Personal experiences with Boost.Graph

I have been experimenting with Boost.Graph since 2006 and I both use the documentation on the Boost website [1] and the book [1].

- Boost.Graph seems like the most type-safe extendable graph library around: learning it will pay off!
- Boost.Graph requires a good compiler, like GCC
- The book [2] will not help a beginner: all code snippets are written 'too smart', where a beginner might prefer four easy-to-understand lines, instead of one using magic. Most code snippets are scattered as part of a complete project, where a beginner might prefer simple short projects
- The website [1] will not help a beginner, for the same reasons as above
- I have never found Boost.Graph documentation or code snippets a beginner would understand (except for (hopefully) at my website), as if nobody understands Boost.Graph and/or everybody that understands Boost.Graph cannot explain simply anymore
- I learned most of Boost.Graph from my IDE (the helpful Qt Creator): by viewing the code that failed, I could understand what was expected for me. I would never have understood Boost.Graph if I would have used a text editor for programming

6.2 To add

Code snippets show include guards , use header_imp instead.

- `std::pair<edge_iterator, edge_iterator> edges(const adjacency_list& g)`
. Returns an iterator pair corresponding to the edges in graph g
- `vertex_descriptor source(edge_descriptor e, const adjacency_list& g)` .
Returns the source vertex of an edge
- `vertex_descriptor target(edge_descriptor e, const adjacency_list& g)` .
Returns the target vertex of an edge
- `degree_size_type in_degree(vertex_descriptor u, const adjacency_list& g)` .
Returns the in-degree of a vertex
- `degree_size_type out_degree(vertex_descriptor u, const adjacency_list& g)` .
Returns the out-degree of a vertex
- `void remove_edge(vertex_descriptor u, vertex_descriptor v, adjacency_list& g)` .
Removes an edge from g
- `void remove_edge(edge_descriptor e, adjacency_list& g)` .
Removes an edge from g
- `void clear_vertex(vertex_descriptor u, adjacency_list& g)` .
Removes all edges to and from u
- `void clear_out_edges(vertex_descriptor u, adjacency_list& g)` .
Removes all outgoing edges from vertex u in the directed graph g (not applicable for undirected graphs)
- `void clear_in_edges(vertex_descriptor u, adjacency_list& g)` .
Removes all incoming edges from vertex u in the directed graph g (not applicable for undirected graphs)
- `void remove_vertex(vertex_descriptor u, adjacency_list& g)` .
Removes a vertex from graph g (It is expected that all edges associated with this vertex have already been removed using `clear_vertex` or another appropriate function.)
